1. INTRODUCTION

1.1. Description

Amtron industrial grade AC series 2.5" PATA SSD delivers all the advantages of flash disk technology with parallel ATA (aka IDE) interface. These PATA SSDs are designed with the highest endurance Single Level Cell (SLC) NAND flash memory. PATA SSDs built with economical yet durable and reliable Multi Level Cell (MLC) NAND flash are also available. These PATA SSDs are offered in wide temperature grade (-40°C to +85°C) and standard temperature grade (0°C to +70°C). Memory capacities are available from 256MB to 64GB (SLC), 4GB to 128GB (pSLC), and 8GB to 256GB (MLC).

2.2. Compliance

Up to ATA/ATAPI-8 (Including S.M.A.R.T)

2.3. MTBF

MTBF (mean time between failures) is a measure of how reliable a hardware product is. Its value represents the average time between a failure repair and the next failure. The unit of MTBF is typically in hours. The higher the MTBF value, the higher the reliability of the product. Please note that a lower MTBF is expected for higher capacity drives. To be conservative, the lowest MTBF is reported in this document. The predicted MTBF for Amtron 2.5" SLC PATA SSD is 3,000,000 hours.

4.5.2. IDE Interface Timing (PIO Mode)

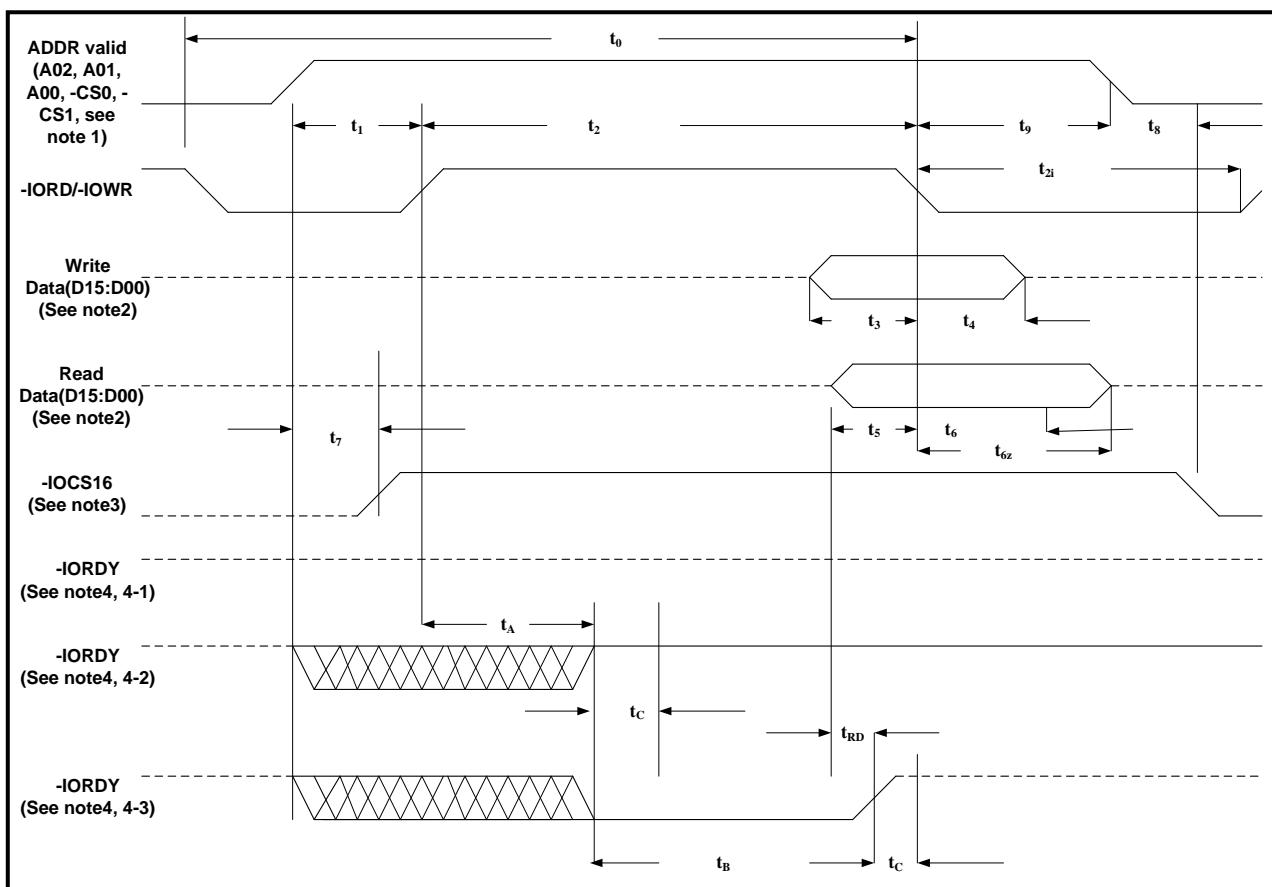

Figure 4-7 IDE Interface Timing (PIO Mode)

NOTES:

1. Device address consists of -CS0, -CS1, and A[02:00]
2. Data consists of D[15::00] (16-bit) or D[07::00] (8 bit)
3. -IOCS16 is shown for PIO modes 0, 1 and 2. For other modes, this signal is ignored.
4. The negation of IORDY by the device is used to extend the PIO cycle. The determination of whether the cycle is to be extended is made by the host after t_A from the assertion of -IORD or -IOWR. The assertion and negation of IORDY is described in the following three cases:
 - Device never negates IORDY: No wait is generated.
 - Device starts to drive IORDY low before t_A , but causes IORDY to be asserted before t_A : No wait generated.
 - Device drives IORDY low before t_A : wait generated. The cycle completes after IORDY is reasserted. For cycles where a wait is generated and -IORD is asserted, the device shall place read data on D15-D00 for t_{RD} before causing IORDY to be asserted.

tC	IORDY assertion to release (max)	5	5	5	5	5	na5	na5	

NOTES:

All timings are in nanoseconds. The maximum load on -IOCS16 is 1 LSTTL with a 50 pF (40pF below 120nsec Cycle Time) total load. All times are in nanoseconds. Minimum time from -IORDY high to -IORD high is 0nsec, but minimum -IORD width shall still be met.

1. t0 is the minimum total cycle time, t2 is the minimum command active time, and t2i is the minimum command recovery time or command inactive time. The actual cycle time equals the sum of the actual command active time and the actual command inactive time. The three timing requirements of t0, t2, and t2i shall be met. The minimum total cycle time requirement is greater than the sum of t2 and t2i. This means a host implementation can lengthen either or both t2 or t2i to ensure that t0 is equal to or greater than the value reported in the device's identify device data. A CompactFlash Storage Card implementation shall support any legal host implementation.

2. This parameter specifies the time from the negation edge of -IORD to the time that the data bus is no longer driven by the CompactFlash Storage Card (tri-state).
3. The delay from the activation of -IORD or -IOWR until the state of IORDY is first sampled. If IORDY is inactive then the host shall wait until IORDY is active before the PIO cycle can be completed. If the CompactFlash Storage Card is not driving IORDY negated at tA after the activation of -IORD or -IOWR, then t5 shall be met and tRD is not applicable. If the CompactFlash Storage Card is driving IORDY negated at the time tA after the activation of -IORD or -IOW R, then tRD shall be met and t5 is not applicable.
4. t7 and t8 apply only to modes 0, 1 and 2. For other modes, this signal is not valid.
5. IORDY is not supported in this mode.

4.5.3. Multi Word DMA

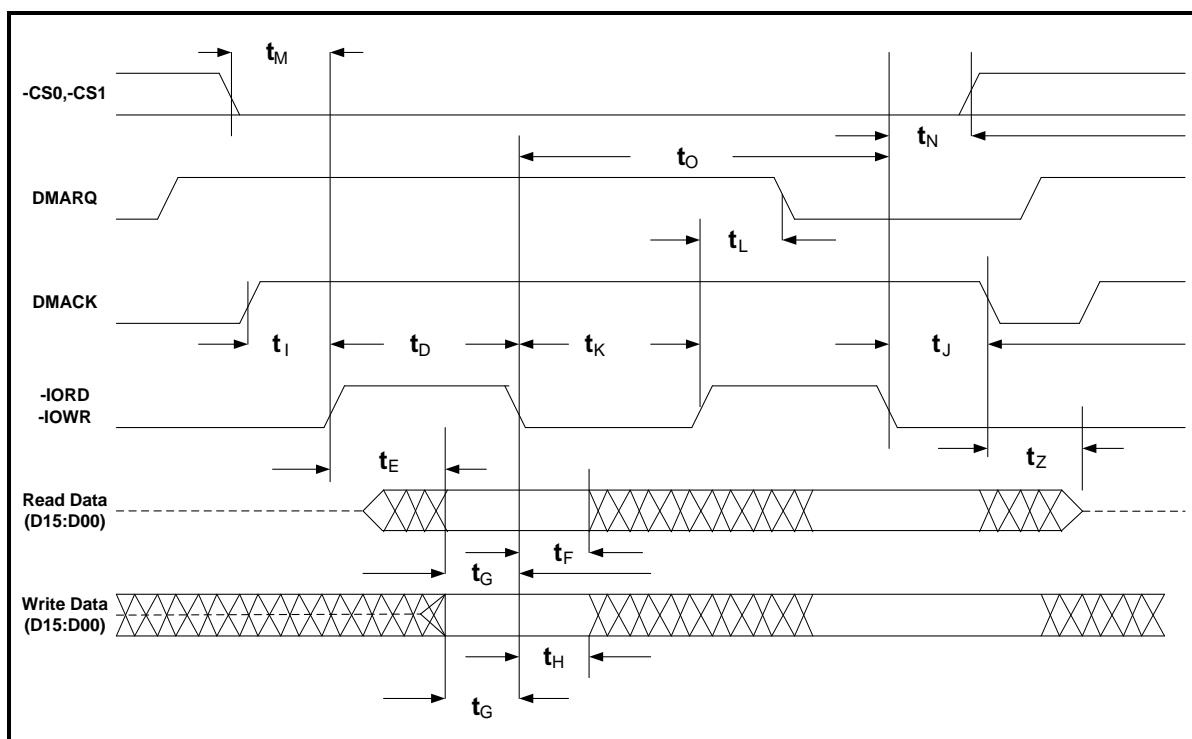

Figure 4-8 Multi Word DMA

NOTES:

All waveforms in this diagram are shown with the asserted state high. Negative true signals appear inverted on the bus relative to the diagram.

1. If the Card cannot sustain continuous, minimum cycle time DMA transfers, it may negate DMARQ within the time specified from the start of a DMA transfer cycle to suspend the DMA transfers in progress and reassert the signal at a later time to continue the DMA operation.
2. This signal may be negated by the host to suspend the DMA transfer in progress.

t_N	CS(1:0) hold	15	10	10	10	10	
t_Z	-DMACK	20	25	25	25	25	

NOTE:

1. t_0 is the minimum total cycle time and t_D is the minimum command active time, while t_{KR} and t_{KW} are the minimum command recovery time or command inactive time for input and output cycles respectively. The actual cycle time equals the sum of the actual command active time and the actual command inactive time. The three timing requirements of t_0 , t_D , t_{KR} and t_{KW} shall be met. The minimum total cycle time requirement is greater than the sum of t_D , t_{KR} and t_{KW} for input and output cycles respectively. This means a host implementation can lengthen either or both of t_D and either of t_{KR} and t_{KW} as needed to ensure that t_D is equal to or greater than the value reported in the device's identify device data. A CompactFlash Storage Card implementation shall support any legal host implementation.

NOTES:

1. The parameters tUI, tMLI, and tLI indicate sender-to-recipient or recipient-to-sender interlocks, i.e., one agent (either sender or recipient) is waiting for the other agent to respond with a signal before proceeding. tUI is an unlimited interlock that has no maximum time value. tMLI is a limited time-out that has a defined minimum. tLI is a limited time-out that has a defined maximum.
2. 80-conductor cabling shall be required in order to meet setup (tDS, tCS) and hold (tDH, tCH) times in modes greater than 2.
3. Timing for tDVS, tDVH, tCVS and tCVH shall be met for lumped capacitive loads of 15 and 40 pF at the connector where the Data and STROBE signals have the same capacitive load value. Due to reflections on the cable, these timing measurements are not valid in a normally functioning system.
4. For all timing modes the parameter tZIORDY may be greater than tENV due to the fact that the host has a pull-up on IORDY- giving it a known state when released.
5. The parameters tDS and tDH for mode 5 are defined for a recipient at the end of the cable only in a configuration with a single device located at the end of the cable. This could result in the minimum values for tDS and tDH for mode 5 at the middle connector being 3.0 and 3.9 ns respectively.
6. This parameter applies to True IDE mode operation only.
